▲□▶ ▲□▶ ▲ □▶ ▲ □▶ ▲ □ ● ● ● ●

## Main result

#### Theorem

Let  $X^5$  be a 5-manifold with a 2-dimensional generic distribution  $D \subset TX$  (real analytic). To such (X,D) is canonically associated a 8-dimensional quaternionic Kähler metric *g*.

• generic : [D,D] is 3-dimensional, [D,[D,D]] = TX

there is a disc bundle

▲□▶ ▲□▶ ▲ □▶ ▲ □▶ ▲ □ ● ● ● ●

such that *g* is defined on a  $F \times (0, \epsilon)$ .

Fiber  $\Delta$  = space of conformal metrics on *D*.

## Main result

#### Theorem

Let  $X^5$  be a 5-manifold with a 2-dimensional generic distribution  $D \subset TX$  (real analytic). To such (X,D) is canonically associated a 8-dimensional quaternionic Kähler metric *g*.

- generic : [D,D] is 3-dimensional, [D,[D,D]] = TX
- there is a disc bundle

$$\begin{array}{c} \Delta \longrightarrow F \\ & \downarrow p \\ & \chi \end{array}$$

- コン・4回ン・4回ン・4回ン・4回ン・4日ン

such that *g* is defined on a  $F \times (0, \epsilon)$ .

Fiber  $\Delta$  = space of conformal metrics on *D*.

## Behavior of g

The asymptotics of g are fixed by (X, D):

$$g \sim rac{ds^2}{s^2} + rac{\gamma_3}{s^3} + rac{\gamma_2}{s^2} + rac{\gamma_1}{s} + \gamma_0$$

The orders of growth correspond to the filtration

$$T_{-3}F = TF \supset T_{-2}F = p^*[D,D] \supset T_{-1}F = p^*D \supset T_0F = \ker p_* = T\Delta,$$

and  $\gamma_i$  is defined on  $T_{-i}F$  with ker  $\gamma_i = T_{-i+1}F$ :

- ker  $\gamma_3 = p^*[D,D]$
- $\gamma_2$  is defined on  $p^*[D,D]$  and ker  $\gamma_2 = p^*D$
- $\gamma_1$  is defined only on  $p^*D$  and ker  $\gamma_1 = \ker p_* = T\Delta$ :

 $\gamma_1 = tautological metric on p^*D$ 

γ<sub>0</sub> is defined along the fibres of p:

 $\gamma_0$  = hyperbolic metric on fibre  $\Delta$ 

and  $\gamma_2$  and  $\gamma_3$  are defined algebraically.

## Behavior of g

The asymptotics of g are fixed by (X, D):

$$g \sim rac{ds^2}{s^2} + rac{\gamma_3}{s^3} + rac{\gamma_2}{s^2} + rac{\gamma_1}{s} + \gamma_0$$

The orders of growth correspond to the filtration

$$T_{-3}F = TF \supset T_{-2}F = p^*[D,D] \supset T_{-1}F = p^*D \supset T_0F = \ker p_* = T\Delta,$$

and  $\gamma_i$  is defined on  $T_{-i}F$  with ker  $\gamma_i = T_{-i+1}F$ :

- ker  $\gamma_3 = p^*[D,D]$
- $\gamma_2$  is defined on  $p^*[D,D]$  and ker  $\gamma_2 = p^*D$
- γ<sub>1</sub> is defined only on p\*D and ker γ<sub>1</sub> = ker p<sub>\*</sub> = T∆:
   γ<sub>1</sub> = tautological metric on p\*D
- γ<sub>0</sub> is defined along the fibres of p:
   γ<sub>0</sub> = hyperbolic metric on fibre Δ
   and γ<sub>2</sub> and γ<sub>3</sub> are defined algebraically.

## Nonlinear Poisson transform

Program with R. Mazzeo.

Let G/H be a symmetric space of noncompact type.

#### Poisson transform

There is a 1:1 correspondence between

- 1. bounded harmonic functions on G/H
- 2. 'functions' on maximal Furstenberg boundary  $G/P_{min}$ .

#### Nonlinear Poisson transform

There should be a 1:1 correspondence between

- 1. complete 'asympt. symmetric' Einstein deformations of G/H
- 2. certain deformations of the parabolic geometry of  $G/P_{min}$ .

Elie Cartan (1910):

parabolic geometry modeled on  $G_2^r/P$  = generic 2-distribution

All the previous constructions of quaternionic Kähler metrics are local versions of this nonlinear Poisson transform: one recovers the other parabolic subgroups by lifting to the minimal parabolic via

 $G/P_{\min} \longrightarrow G/P.$ 

#### Question 1

Find a unified construction of a local quaternionic Kähler metric starting from a parabolic geometry modeled on a boundary G/P of a quaternionic Kähler symmetric space G/H of noncompact type. (Remind there is one such symmetric space for each simple complex Lie group)

More modest question: unify the existing constructions.

### Geodesics

Some of these constructions rely on the use of a space of geodesics (LeBrun's constructions,  $G_2$ ).

#### Proposition

The only examples which admit a space of geodesics are:

- conformal geometries (LeBrun's examples)
- the  $G_2/P$  example
- $SO(3,4)/P_3$  with  $P_3$  fixing a totally isotropic 3-plane.

#### Definition

A generic distribution  $D^2 \subset TX^5$  is **Zoll** if all the geodesics are closed.

#### Question 2

- 1. are there other Zoll 2-distributions in dimension 5?
- 2. if yes, when can the quaternionic Kähler metric be extended to a complete quaternionic Kähler metric ? (ie when is the Einstein metric quaternionic Kähler ?)
  - $\longrightarrow$  might get 'positive frequencies'

Same question in the other cases with geodesics: in particular for G = SO(4, 2), the question becomes:

are there other Zoll conformal Lorentzian metrics on compactified Minkowski 4-space ?

## Sketch of proof of the Theorem

## The twistor space of $G_2/SO(4)$ is $N = (G_2/P_2)^{\mathbb{C}}$ .

Complexify the whole situation:

## Sketch of proof of the Theorem

The twistor space of  $G_2/SO(4)$  is  $N = (G_2/P_2)^{\mathbb{C}}$ . Complexify the whole situation:

э

# Must construct a 8-dimensional family of rational curves extending the 5-dimensional family

## $C_x = q(p^{-1}(x)),$ normal bundle: $\mathcal{O} \oplus \mathcal{O} \oplus \mathcal{O} \oplus \mathcal{O}(1).$

One must consider  $C_x$  as non reduced (doubled in the  $\mathcal{O}(1)$  direction).

As such it has a 8-dimensional family of deformations.

But: need also normal bundle to be  $\mathscr{O}(1) \oplus \mathscr{O}(1) \oplus \mathscr{O}(1) \oplus \mathscr{O}(1)$ .

#### Parabolic dilations

One uses the parabolic geometry of (X, D): the parabolic dilations

$$h_t(x_1, x_2, x_3, x_4, x_5) = (tx_1, tx_2, t^2x_3, t^3x_4, t^3x_5)$$

on a small open set U have the property that

$$h_t^*D \xrightarrow[t \to 0]{} \text{model } G_2/P.$$

It follows that

$$h_t^*N(U) = N(h_t^*U) \xrightarrow[t \to 0]{} model N(G_2/P).$$

In particular the rational curves converge to that of the model and therefore have the same normal bundle  $\mathscr{O}(1) \oplus \mathscr{O}(1) \oplus \mathscr{O}(1) \oplus \mathscr{O}(1)$ .

The behavior of the metric is found by inverse twistor transform.

#### Parabolic dilations

One uses the parabolic geometry of (X, D): the parabolic dilations

$$h_t(x_1, x_2, x_3, x_4, x_5) = (tx_1, tx_2, t^2x_3, t^3x_4, t^3x_5)$$

on a small open set U have the property that

$$h_t^*D \xrightarrow[t \to 0]{} model G_2/P.$$

It follows that

$$h_t^*N(U) = N(h_t^*U) \xrightarrow[t \to 0]{} \text{model } N(G_2/P).$$

In particular the rational curves converge to that of the model and therefore have the same normal bundle  $\mathcal{O}(1) \oplus \mathcal{O}(1) \oplus \mathcal{O}(1) \oplus \mathcal{O}(1)$ .

The behavior of the metric is found by inverse twistor transform.
